Oxidant speciation and anionic ligand effects in the gold-catalyzed oxidative coupling of arenes and alkynes

Hofer, Manuel ; de Haro, Teresa ; Gómez-Bengoa, Enrique ; Genoux, Alexandre ; Nevado, Cristina

Abstract: The mechanism of the gold-catalyzed oxidative cross-coupling of arenes and alkynes has been studied in detail combining stoichiometric experiments with putative reaction intermediates and DFT calculations. Our data suggest that ligand exchange between the alkyne, the Au(I)-catalyst and the hypervalent iodine reagent is responsible for the formation of both, a Au(I)-acetylide complex as well as a more reactive "non-symmetric" I(III) oxidant, responsible for the crucial Au(I)/Au(III) turnover. Further, the reactivity of the in situ generated Au(III)-acetylide complex is governed by the nature of the anionic ligands transferred by the I(III) oxidant: while halogen ligands remain unreactive, acetato ligands are efficiently displaced by the arene to yield the observed Csp2-Csp cross-coupling products through an irreversible reductive elimination step. Finally, the nature of competitive processes and catalyst deactivation pathways has also been unraveled. This detailed investigation provides insights not only on the specific features of the species involved in oxidative gold-catalyzed cross couplings but also highlights the importance of both ancillary and anionic ligands on the reactivity of the key Au(III) intermediates.

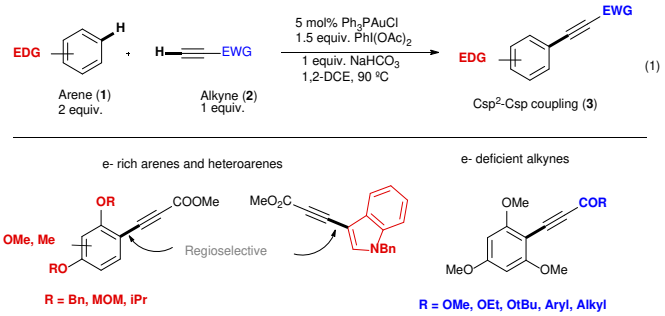
The mechanism of the gold-catalyzed oxidative cross-coupling of arenes and alkynes has been studied in detail combining stoichiometric experiments with putative reaction intermediates and DFT calculations. Our data suggest that ligand exchange between the alkyne, the Au(I)-catalyst and the hypervalent iodine reagent is responsible for the formation of both, a Au(I)-acetylide complex as well as a more reactive "non-symmetric" I(III) oxidant, responsible for the crucial Au(I)/Au(III) turnover. Further, the reactivity of the *in situ* generated Au(III)-acetylide complex is governed by the nature of the anionic ligands transferred by the I(III) oxidant: while halogen ligands remain unreactive, acetato ligands are efficiently displaced by the arene to yield the observed Csp^2-Csp cross-coupling products through an irreversible reductive elimination step. Finally, the nature of competitive processes and catalyst deactivation pathways has also been unraveled. This detailed investigation provides insights not only on the specific features of the species involved in oxidative gold-catalyzed cross couplings but also highlights the importance of both ancillary and anionic ligands on the reactivity of the key Au(III) intermediates.

Introduction

Aryl alkynes have found widespread use as building blocks in the synthesis of numerous natural products, bioactive molecules and organic materials.[1] In recent years, metal-catalyzed Csp^2-H bond functionalizations have been explored as an alternative strategy to classical Pd-catalyzed cross-coupling reactions for the efficient construction of Csp^2-Csp bonds.[2] These approaches are attractive because they avoid the otherwise necessary pre-functionalization of the aromatic partner. However, and in contrast to the large body of metal-catalyzed Csp^2-H arylation reactions,[3] the direct Csp^2-H alkynylation of arenes has been much less explored. Few examples though have shown the viability of this strategy.[4] In 2010, the Cu-catalyzed direct alkynylation of electron deficient polyfluoroarenes with terminal alkynes using O_2 as oxidant was reported by Su et al.[5] Despite its efficiency, the reaction is barely catalytic and relies on the acidity of the Csp^2-H bond in the arene substrate. A different approach focused on the stoichiometric use of alkynyliodonium species as an electrophilic source of acetylenic moieties in the presence of catalytic amounts of late transition metals as demonstrated by Waser et al.[6] In this context, our group reported an oxidative alkynylation of arenes via Au-catalyzed C-H functionalization of both Csp- and Csp^2-H bonds (equation 1, Scheme 1).[7] One of the most remarkable features of this protocol was the use of ''deactivated'' electron rich arenes and electron deficient alkynes as coupling partners. A catalytic amount of Ph_3PAuCl in combination with commercially available $PhI(OAc)_2$ as stoichiometric oxidant was found to be effective in producing new Csp^2-Csp bonds.[8] A stoichiometric version of this transformation had been already described by Fuchita and co-workers back in 2001.[9]

Scheme 1. Au-Catalyzed Alkynylation of Arenes



In the catalytic version, a hypervalent iodine reagent[10] was selected as oxidant on the basis of significant evidence that these species could promote Pd(II)/Pd(IV) catalytic cycles.[11] We thus anticipated that a Au(I)/Au(III) catalytic turnover could be implemented under the reaction conditions. Furthermore, the ability of Au(III) species to trigger Csp^2-H activation in electron rich arenes is also well established.[9,12] Although Au(I)/Au(III)-catalyzed reactions have recently emerged as powerful tools for C-C cross couplings,[13] with few notable exceptions,[14] the mechanistic understanding of these processes is still limited and the characterization of putative intermediates scarce. We report herein a detailed investigation aiming to elucidate the factors governing both, reactivity and selectivity in these transformations.

In our previous work,[7] the mechanistic rationale involved: (i) an equilibrium between the free alkyne and the Au catalyst with the aid of base to form a Au(I)-acetylide complex (**I**); (ii) oxidation of **I** with $PhI(OAc)_2$ to form Au(III) species **II**; (iii) an arene auration to produce intermediate **III** which evolves via reductive elimination (iv) yielding

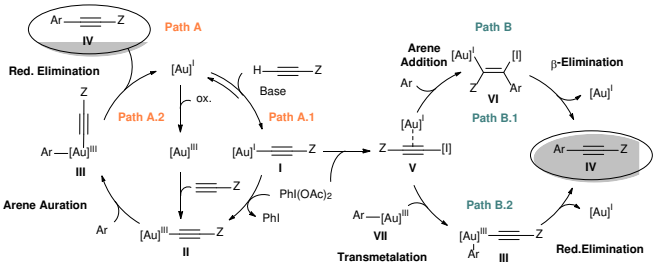
product **IV** (Scheme 2, path A.1). Alternatively, in line with Waser´s reports on the stoichiometric use of alkynyliodonium salts,[6] a ligand exchange between $PhI(OAc)_2$ and Au(I)-acetylide (**I**) to give an alkynyliodonium intermediate (**V**) could also be proposed. Arene addition to give **VI** followed by *β*-Au elimination would then furnish product **IV** as shown in path B.1 of Scheme 2. Alternatively, transmetalation between alkynyliodonium salt **V** and putative aryl-Au(III) species (**VII**) produced *in situ* within the oxidative reaction media[12] could also deliver intermediate **III**, which would yield the observed products after reductive elimination as shown in Scheme 2, path B.2.

Scheme 2. Plausible Mechanisms for Au-Catalyzed Alkynylation of Arenes



Our preliminary study left opened several key questions: first and foremost, the role of $PhI(OAc)_2$ needed to be established, whether it functioned as a stoichiometric oxidant to achieve the Au(I)/Au(III) turnover or as an electrophilic source to exchange and then cross-couple the alkyne to an electron rich arene, or both.[6d] In addition, the order of steps needed to be clarified as to whether the transfer of the alkyne to the gold(I) complex (path A.1) or a direct oxidation (path A.2) was involved in the initial step of the catalytic cycle. Furthermore, neither detailed information about the metal coordination sphere in the proposed Au(III) intermediates **II** and **III** nor about the oxidant environment was available from these initial investigations.[7]

Results and Discussion

Initial experiments[15] to investigate the feasibility of pathways B.1 and B.2 focused on alkynyliodonium salts (**V**) in order to reveal their potential role as intermediates in these transformations.

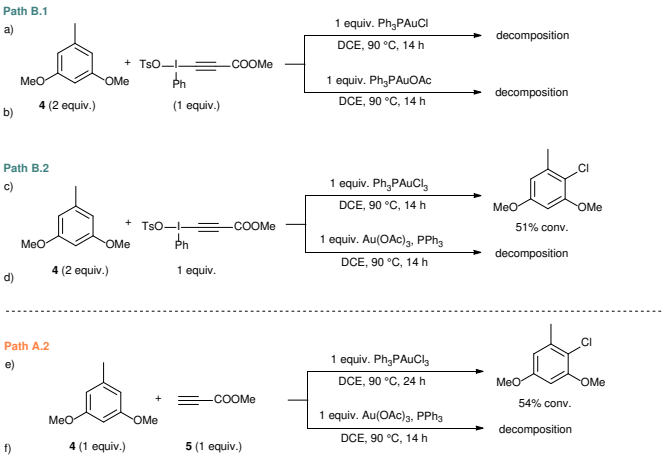


Figure 1. a-d) Stoichiometric experiments involving alkynyliodonium species (path B.1 and B.2 in Scheme 2). e-f) Stoichiometric experiments regarding path A.2.

Treatment of methyl 3-(phenyl(tosyloxy)-λ^3-iodanyl)propiolate with stoichiometric amounts of 3,5-dimethoxytoluene (**4**) and Ph_3PAuCl or $Ph_3PAuOAc$ at 90 °C did not furnish the desired Csp^2-Csp cross coupling product and only decomposition of the alkynyliodonium salt was detected (Figure 1a, 1b). Identical experiments in the presence of gold(III) complexes like Ph_3PAuCl_3 or $Au(OAc)_3/PPh_3$ showed a similar outcome (Figure 1c, 1d). Interestingly, in case of Ph_3PAuCl_3 formation of 2-chloro-1,5-dimethoxy-3-methylbenzene as by-product could be observed.[12a] These control experiments (Section 2 in the SI) led us to rule out pathways B.1 and B.2 and the participation of alkynyliodonium species **V** as intermediates in these transformations.

Experiments to investigate pathway A.2 involved the participation of the alkyne in presence of gold(III) species. However, stoichiometric experiments of 3,5-dimethoxytoluene (**4**), methyl propiolate (**5**) and Ph_3PAuCl_3 or $Au(OAc)_3/PPh_3$ at 90°C showed the formation of the arylchloride in case of Ph_3PAuCl_3 but no participation of the alkyne (Figure 1e, 1f). To explore the direct oxidation of the initial catalyst, Ph_3PAuCl was treated with excess of $PhI(OAc)_2$ at 90 °C. However, no reaction was observed even after prolonged heating and just Ph_3PO could be detected in trace amounts (Figure S2-3 in the SI). These experiments suggest that the neutral Ph_3PAuCl complex used as catalyst is scarcely oxidized by $PhI(OAc)_2$ under the reaction conditions, in contrast to previous results obtained for $PhICl_2$ which furnished Ph_3PAuCl_3 in 96% yield even at room temperature.[16] In situ oxidation of the Au(I) catalyst also seems to be at the outset of the Au-catalyzed oxidative oxo- and aminoarylation of alkenes with boronic acids.[14a-b] However, the results described herein clearly indicate that the present alkynylation reaction proceeds, at least on the outset, through an alternative reaction mechanism.

Formation and Reactivity of Au(I)-acetylide (8)

To investigate path A.1, a careful spectroscopic analysis (^1H and ^{31}P NMR) of the reaction mixture stemming from the reaction between 3,5-dimethoxytoluene (**4**) and methyl propiolate (**5**) under the standard conditions (5 mol% Ph_3PAuCl, 1.5 equiv. $PhI(OAc)_2$, 1 equiv. $NaHCO_3$) was performed. The reaction showed the presence of three species: the initial catalyst Ph_3PAuCl, $[(Ph_3P)_2Au]Cl$ (**7**) and a $Ph_3PAu(C{\equiv}C\text{-}CO_2Me)$ complex (**8**) (Figure 2a and S4-5 in the SI).

Complex **8** appears already after the first minutes of the reaction and it disappears towards the end whereas Ph_3PAuCl and **7** are present after the starting materials have been completely consumed. Ph_3PO could not be detected in the reaction mixture. These results indicate that the phosphine ligand remains bound to the metal center and thus does not get oxidized by $PhI(OAc)_2$ in appreciable quantities. In situ generated phosphine-free Au(III) species have been proved to be the productive intermediates in the recently reported Au-catalyzed cross coupling reaction of aryl silanes with arenes.[14c] Interestingly, a catalytic reaction in the presence of IPrAuCl gave no product conversion, thus highlighting the importance of the ancillary ligand in these transformations.

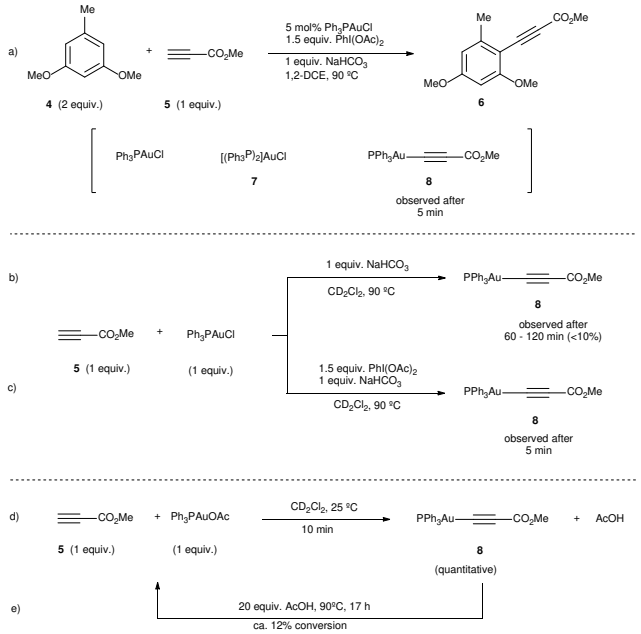

Figure 2. a) Standard catalytic reaction. b,c) Experiments towards the formation of Au(I)-acetylide **8** from Ph_3PAuCl and alkyne **5** in the absence or presence of $PhI(OAc)_2$, respectively. d,e) Reactivity of $Ph_3PAuOAc$ towards methyl propiolate (**5**).

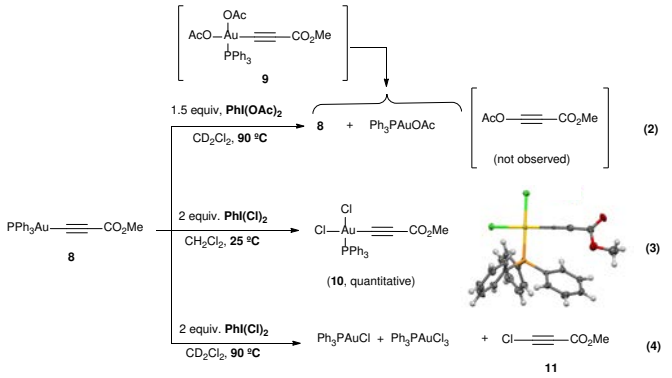
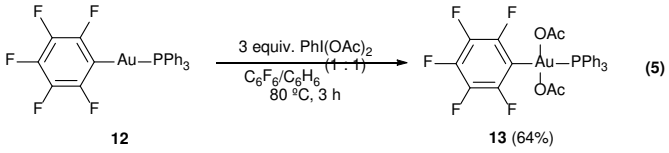
Once the species detected during the reaction had been identified, we decided to interrogate in detail both, the mechanism for the formation, as well as the reactivity of the Au(I)-acetylide complex **8**. We monitored the formation of **8** from Ph_3PAuCl, methyl propiolate (**5**) and $NaHCO_3$ by both ^1H and ^{31}P NMR performing the reaction in CD_2Cl_2. Experimentally, the formation of complex **8** is not a favorable process, and even after prolonged heating, it could only be detected in marginal amounts (Figure 2b and Figure S6-7 in the SI). In contrast, the same reaction in the presence of $PhI(OAc)_2$ revealed the presence of **8** after only 5 minutes (Figure 2c and Figures S8-9 in the SI), in line with the spectroscopic analysis of a catalytic reaction (Figure 2a). Interestingly, the reaction of $Ph_3PAuOAc$ with **5** proceeded quantitatively at room temperature in the absence of oxidant producing **8** and AcOH in only 10 minutes (Figure 2d). On the other hand, the reverse reaction, although not unfeasible, is not a favorable process. These observations suggested an additional and unexpected new role of the oxidant in the initial steps of the reaction: $PhI(OAc)_2$ favors the formation of the observed complex **8** (Figure S10-13 in the SI).

The reactivity of the Au(I)-acetylide **8** was studied next. Gold acetylides have been proposed as productive reaction intermediates in different transformations including the formation of Au vinylidenes[17] or the Au-catalyzed homo-[18] and heterocoupling[19] of alkynes. The reaction of **8** with $PhI(OAc)_2$ in CD_2Cl_2 was monitored by ^1H and ^{31}P NMR. Indeed, no conversion was observed up to 60 °C while only very low conversion into $Ph_3PAuOAc$ and Ph_3PAuCl was detected even after prolonged heating at 90 °C (equation 2 and Figures S14-15 in the SI)[20]. These results indicate, that **8** is hardly oxidized with $PhI(OAc)_2$ and also that the putative oxidation product $Ph_3PAu(C{\equiv}C\text{-}CO_2Me)(OAc)_2$ **9**, is rather unstable under the reaction conditions undergoing rapid reductive elimination to give $Ph_3PAuOAc$ and 3-(acetyloxy)-methyl propiolate (which decomposes *in situ* due to its highly labile nature).

In sharp contrast, the reaction of **8** in the presence of $PhICl_2$ cleanly proceeded at room temperature to give *cis*-$Ph_3PAu(C{\equiv}C\text{-}CO_2Me)(Cl)_2$ (**10**), whose structure could be confirmed by X-ray diffraction analysis (equation 3). These results not only showcase the different oxidizing abilities of $PhI(OAc)_2$ vs. $PhICl_2$ but also the influence of the ligand transferred by the hypervalent iodine reagent on the stability of the corresponding Au(III) intermediates produced in the reaction mixture. When **8** and $PhICl_2$ were stirred at higher temperature, reductive elimination on **10** occurred, furnishing Ph_3PAuCl, which is oxidized in the presence of the remaining oxidant to Ph_3PAuCl_3. In this case, the by-product stemming from reductive elimination (i.e. 3-chloro-methyl propiolate **11**[21]) could be clearly observed (equation 4 and Figures S20-21 in the SI).



Due to the labile nature of complex **9**, we decided to seek an alternative model system to study the reactivity of the putative Au(III) intermediates produced during the aryl alkynylation reaction. $Ph_3PAuC_6F_5$ (**12**) was selected expecting that the electron deficient nature of the pentafluorophenyl ligand could mimic that of the propiolate unit while offering a more stable platform for the isolation of gold(III) species. Reaction of $Ph_3PAuC_6F_5$ (**12**) with $PhI(OAc)_2$ in a 1:1 mixture of hexafluorobenzene/benzene at 80 °C, delivered *trans*-$Ph_3PAu(C_6F_5)(OAc)_2$ (**13**) in 64% yield according to our previously reported procedure (equation 5).[22]



Reactivity of putative Au(III)-intermediates

We set out to examine the reactivity of complexes **10** and **13** towards the species present in the media during the standard aryl alkynylation reaction, namely: methyl propiolate (**5**), Au(I)-acetylide complex (**8**) and electron-rich arenes in a stoichiometric fashion. The results of this study have been summarized in Table 1. Interestingly, *trans*-$Ph_3PAu(C_6F_5)(OAc)_2$ (**13**) reacted with methyl propiolate (**5**) at 25 °C to give methyl 3-(pentafluorophenyl)-prop-2-ynoate (**14**) in 68% yield together with Au(I)-acetylide complex **8** as a result of the double replacement of both acetato ligands with free alkyne followed by reductive elimination (See Fig. S22-23 in the SI). The reaction of **13** with complex **8** was also illustrative, providing **14** in 62% yield together with $Ph_3PAuOAc$. Since no Au(I)-acetylide complex **8** was detected at the end of the reaction, we have to assume that upon a first Au(I)/Au(III) transmetalation (which could also be described as a Au(I)/Au(III) ligand exchange reaction), Csp^2-

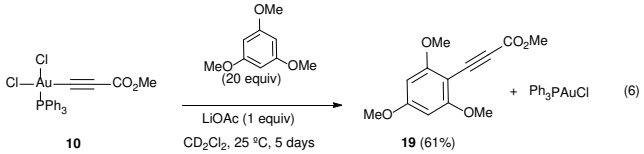
Csp reductive elimination occurs fast, preventing a second ligand transfer between the different gold species (See Fig. S24-25 in the SI). Finally, the reactions of **13** with 1,3,5-trimethoxybenzene, 1,3-dimethoxytoluene **4** and *N*-methyl indole were also enlightening as they proceeded efficiently towards the corresponding cross-coupling products **15**, **16** and **17** in 85, 74 and 85% yield, respectively.[16b,23]

Table 1. Comparison of reactivity between Au(III)-bis-chloro vs. bis-acetato complexes.

REACTIVITY OAc vs. Cl	 **13**	 **10**
 **5**	 **14** (68%)[a]	No Reaction[d]
 **8**	 **14** (62%)[b]	 **18** (quant.)[e]
 **4**	 **15** (85%)[b] **16** (74%)[b,c]	No Reaction[f]
	 **17** (85%)[b]	

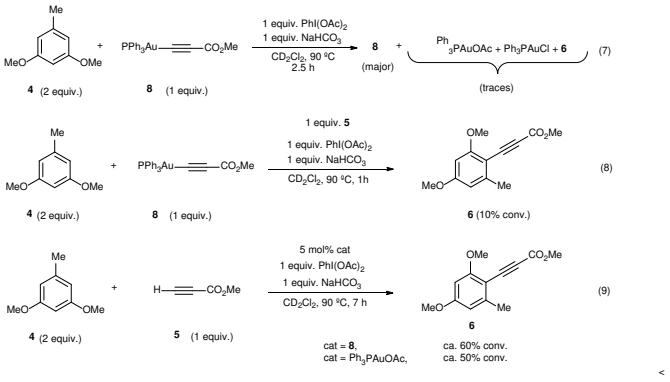
[a] Au(I)-acetylide **8** was also detected. [b]$Ph_3PAuOAc$ was also detected. [c]Compound **16** is obtained as a 0.6:1 mixture of regioisomers. [d]Traces of alkyne homocoupling product **18** were detected. [e]Ph_3PAuCl was also detected. [f]See also ref. 16b.

The reactivity pattern observed for *cis*-dichloro(methoxy-carbonylethynyl)(triphenylphosphine)-gold(III) (**10**) turned out to be completely different as shown on the right column of Table 1. In contrast to **13**, complex **10** did not react with methyl propiolate (**5**) (Fig. S26-27 in the SI) although it underwent transmetalation with Au(I)-acetylide complex **8** even at -25 °C to give alkyne homocoupling product **18**[24] and Ph_3PAuCl. As in the previous case, only one Cl/alkyne ligand exchange took place (Fig. S28-29 in the SI). Also in contrast to **13**, *cis*-$Ph_3PAu(C{\equiv}C\text{-}CO_2Me)(Cl)_2$ (**10**) proved to be completely unreactive towards electron-rich aromatic nucleophiles even after prolonged heating at 130 °C (Fig. S30-31 in the SI).[16b,25] The experiments summarized in Table 1 showcase the strong differences in reactivity for diacetato-Au(III) vs. dichloro-Au(III) complexes[26] and highlight the importance of the oxidant of choice, i.e. the ligand that ultimately the oxidant transfers onto the metal center, for a productive reaction outcome. In line with this hypothesis, replacement of the chloro ligands in **10** by reaction with 1 equivalent of LiOAc in the presence of 1,3,5-trimethoxybenzene in excess resulted in the clean formation of Ph_3PAuCl and alkynylation product **19** in 61% yield (equation 6).



10 **19** (61%) (6)

Additional stoichiometric experiments with Au(I)-acetylide complex **8** were designed. When the reaction of 3,5-dimethoxytoluene (**4**) was run using Au(I)-acetylide **8** as stoichiometric alkynylating agent in the presence of $PhI(OAc)_2$ and $NaHCO_3$ only traces of the desired cross coupling product **6** were detected (equation 7 and Fig. S32-33 in the SI). In contrast, when methyl propiolate (**5**) was incorporated in the reaction, arylalkyne product **6** was clearly observed after only one hour even if in low conversion (equation 8 and Fig. S34-35 in the SI). A catalytic version of this reaction using 5 mol% of **8** or $Ph_3PAuOAc$ also afforded **6** although again, in a much less efficient manner compared to the standard conditions (equation 9 and Fig. S36-37 in the SI).



These experiments clearly suggest that the presence of free alkyne in the reaction mixture favors a productive reaction outcome *and together with equation 2 highlight that neither $PhI(OAc)_2$ is an efficient oxidant for **8** nor the putative* $Ph_3PAu(C{\equiv}C\text{-}CO_2Me)(OAc)_2$ (**9**) *complex is a highly competent reaction intermediate.* Additionally, the reactions shown in Figure 1b-d indicated that the oxidant is involved in the activation of the alkyne. We hypothesized that the formation of **8** could occur by ligand exchange on Ph_3PAuCl in the presence of $PhI(OAc)_2$ to form $Ph_3PAuOAc$ which rapidly activates the alkyne **5** to form **8** and AcOH, that is then quenched by $NaHCO_3$ present in the reaction media (Figure 1d). This proposal is supported by recent experiments of Shi et al., showing the formation of $R_3PAuOAc$ in presence of R_3PAuCl and $PhI(OAc)_2$ by MALDI-MS analysis.[27] Thus, to gain a deeper insight into the specific nature of the individual steps involved in these transformations, DFT calculations and additional control experiments were carried out.

DFT Studies and Characterization of the Oxidizing Species

In line with the experimental observations summarized in Figure 2, calculations confirmed that formation of Au(I)-acetylide **8** from Ph_3PAuCl in the absence of oxidant is a highly unfavorable process even in the presence of base (19.1 kcal/mol, Figure 3a). The lack of reactivity observed for Ph_3PAuCl in the presence of $PhI(OAc)_2$ could also be confirmed. A potential Au(Cl)/I(OAc) exchange is also disfavored (+12.8 kcal/mol), and thus such an equilibrium would be strongly shifted towards the starting materials (Figure 3b). When alkyne is added into the system, the energies of these two equilibria remain unchanged. However, the trace amounts of $Ph_3PAuOAc$ that could be produced rapidly react with the free alkyne present in the media to give Au(I)-acetylide complexes and acetic acid, which will be quenched with the base present in the reaction (Figure 3c and Figure 1d). The energy for this process decreases to +6.3 kcal/mol. Thus, the second equilibria will drive the first one towards the right, influenced by the presence of free alkyne. Furthermore, the in situ generated PhI(OAc)(Cl) intermediate presents a much lower activation energy towards the oxidation of Au(I) acetylide via **TS_3** (+20.1 kcal/mol) compared to $PhI(OAc)_2$ via **TS_3´**(+29.2 kcal/mol) (Figure 3d).

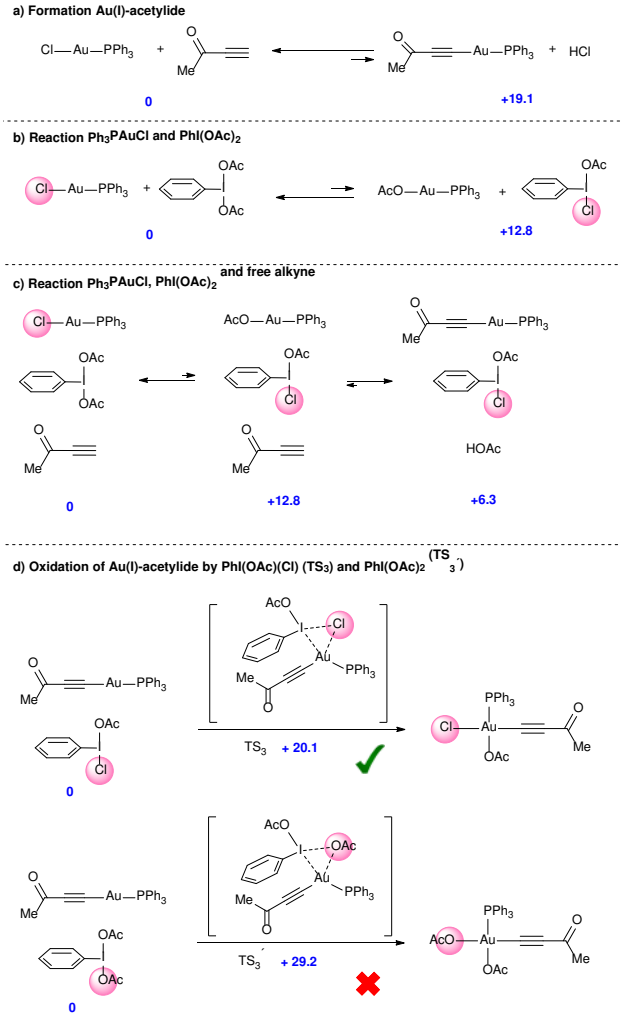


Figure 3. Computed Gibbs Free energy values (kcal/mol) for the potential reaction between Ph_3PAuCl, alkyne (methyl alkynyl ketone) and $PhI(OAc)_2$ calculated with the M06 functional.

Stoichiometric experiments were subsequently designed to support the hypothesis of a Au(Cl)/I(OAc) ligand exchange triggered by the presence of free alkyne and the formation of a more reactive "non-symmetrical" oxidant. In an attempt to detect such species by highly sensitive ^{19}F NMR spectroscopy, a fluorine-containing iodonium diacetate, namely *m*-F-$C_6H_4I(OAc)_2$ (**20**), was synthesized.[28]

The *in situ* kinetic studies of a reaction between **20**, methyl propiolate (**5**) and Ph_3PAuCl revealed the consumption of **20** and the simultaneous formation of a new product with a characteristic ^{19}F signal at 107.5 ppm which was assigned to *m*-F-$C_6H_4I(OAc)(Cl)$ (**21**) (Figure 4a-b). The oxidizing potential of **21** is higher than that of **20** as already revealed by the DFT calculations (Figure 3d) and thus the Au(I)-acetylide complex **8** which has been generated *in situ,* can be slowly oxidized even at room temperature, thus preventing the accumulation of **21** in the reaction media. In the absence of other species, an OAc-alkyne ligand exchange reaction on the Au(III)-acetylide intermediate (red path) or a transmetalation between the Au(I) and Au(III)-acetylide species coexisting in the reaction media (blue path) could explain the formation of homocoupling product **18**, which is produced in a comparable ratio to that in which **20** is consumed (Figure 4c). Additional experiments were carried out to support the proposed structure of compound **21**: the reaction of *m*-F-$C_6H_4I(Cl)_2$ with 1 equivalent of AgOAc delivered, after only 5 min, the same species observed in the ^{19}F NMR spectrum , thus confirming the proposed composition of the "non-symmetric" oxidant (Figure 4d). (For these and additional control experiments, see section 3.8 in the SI).

To confirm the ability of a chloride transfer from Ph_3PAuCl to $PhI(OAc)_2$, the standard cross-coupling reaction was performed in the presence of 1 equivalent of $(n\text{-}Bu)_4NCl$ (see section 3.9 in the SI). As expected, the initial excess of chloride in the reaction mixture inhibited the formation of the desired cross-coupling product. In turn, 2-chloro-3,5-dimethoxytoluene could be detected, pointing towards in situ generated **21**, which in this case is produced in abundant quantities in the reaction media, as chlorinating agent. In line with these results, in the absence of Cl available for ligand exchange, the performance of **8** or $Ph_3PAuOAc$ as catalysts (equation 9) delivered the cross-coupling product in lower yield compared to the standard conditions.

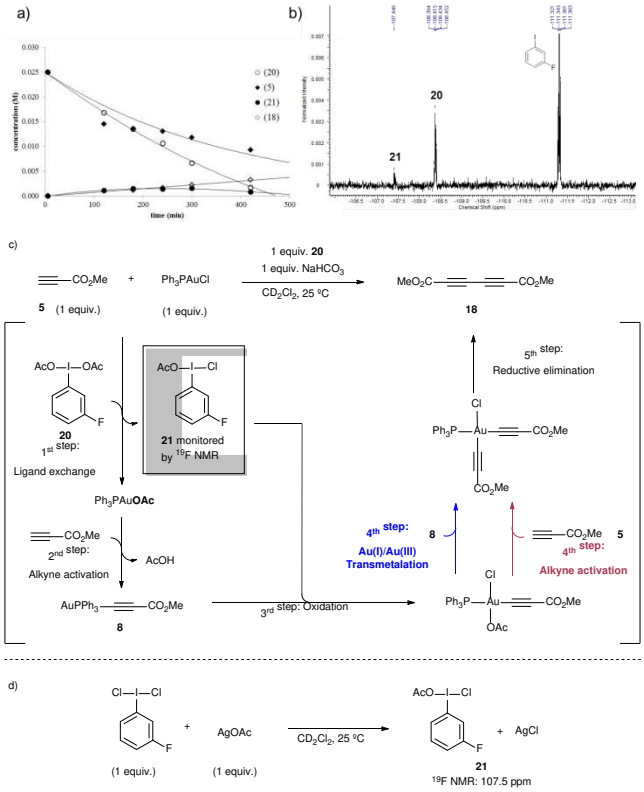

Figure 4. Formation of "non-symmetric" I(III) species by reaction of *m*-F-$C_6H_4I(OAc)_2$ **20** with Ph_3PAuCl and methyl propiolate (**5**): a) Evolution of the temporal concentration of reactants, intermediates and product. b) ^{19}F NMR traces of the reaction mixture. c) Rationalization of the observed species. d) Alternative synthesis and characterization of *m*-F-$C_6H_4I(OAc)(Cl)$ (**21**).

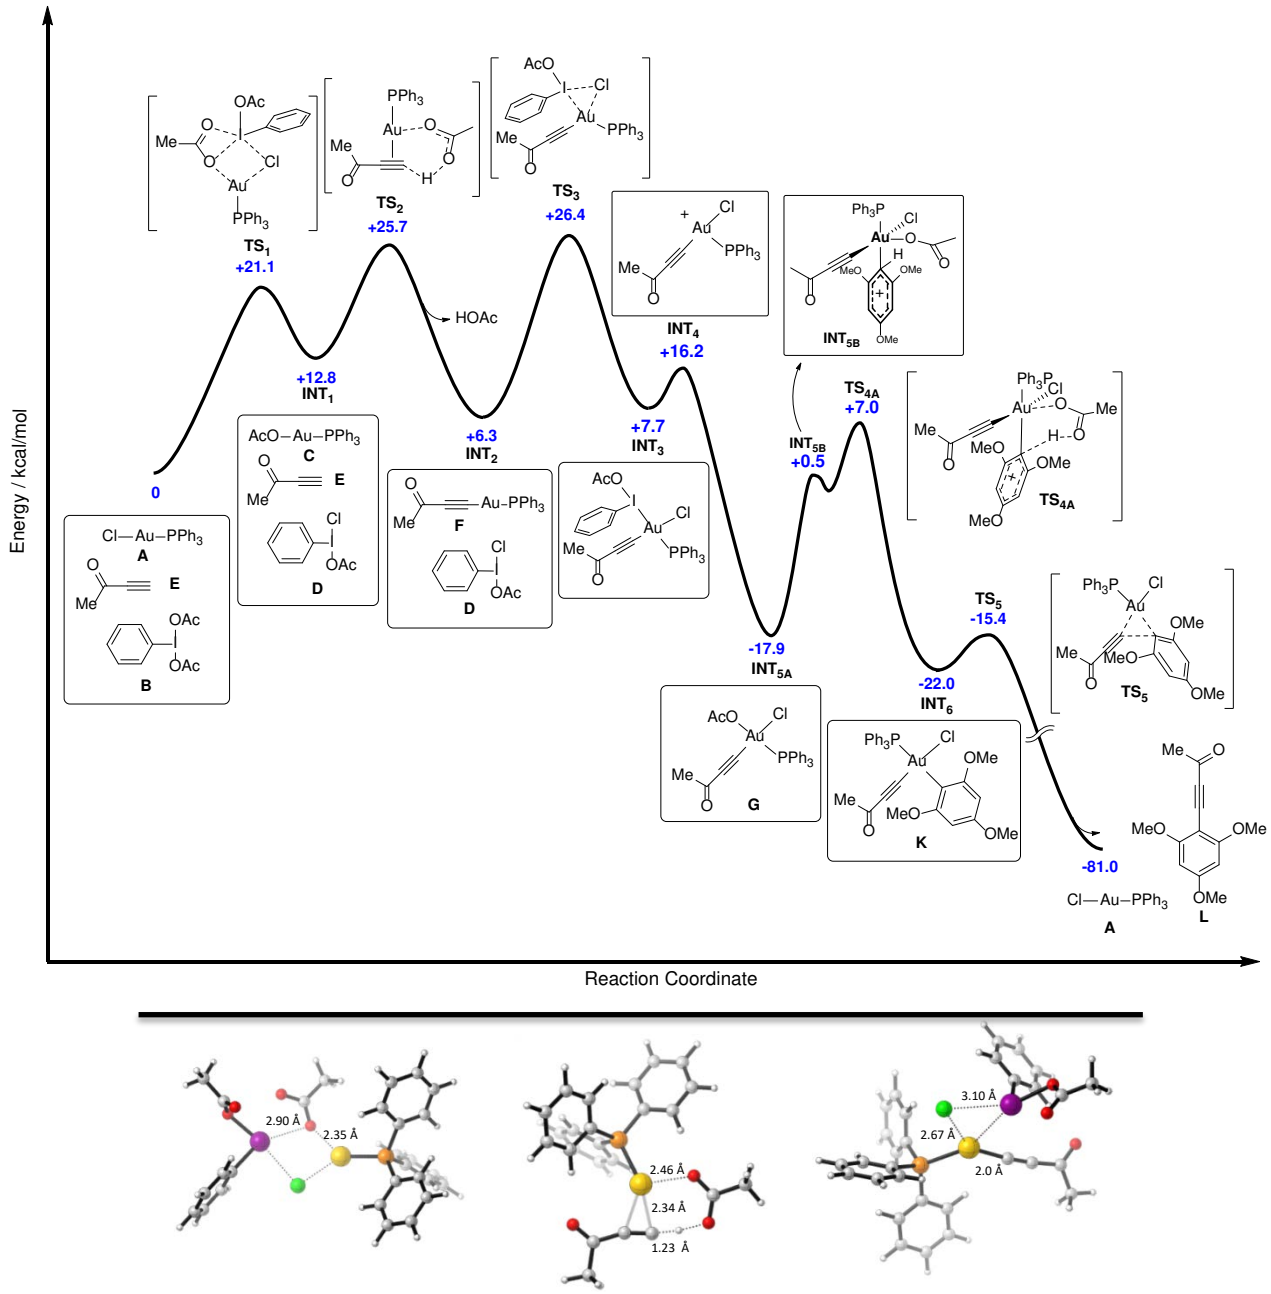

Figure 5. Top: complete energy profile for the reaction between Ph_3PAuCl, alkyne (methyl alkynyl ketone), $PhI(OAc)_2$ and arene (1,3,5-trimethoxybenzene). Gibbs Free energy values in blue calculated with the M06 functional. Bottom: structures of transition states **TS_1**, **TS_2** and **TS_3** (left to right) highlighting the relevant distances.

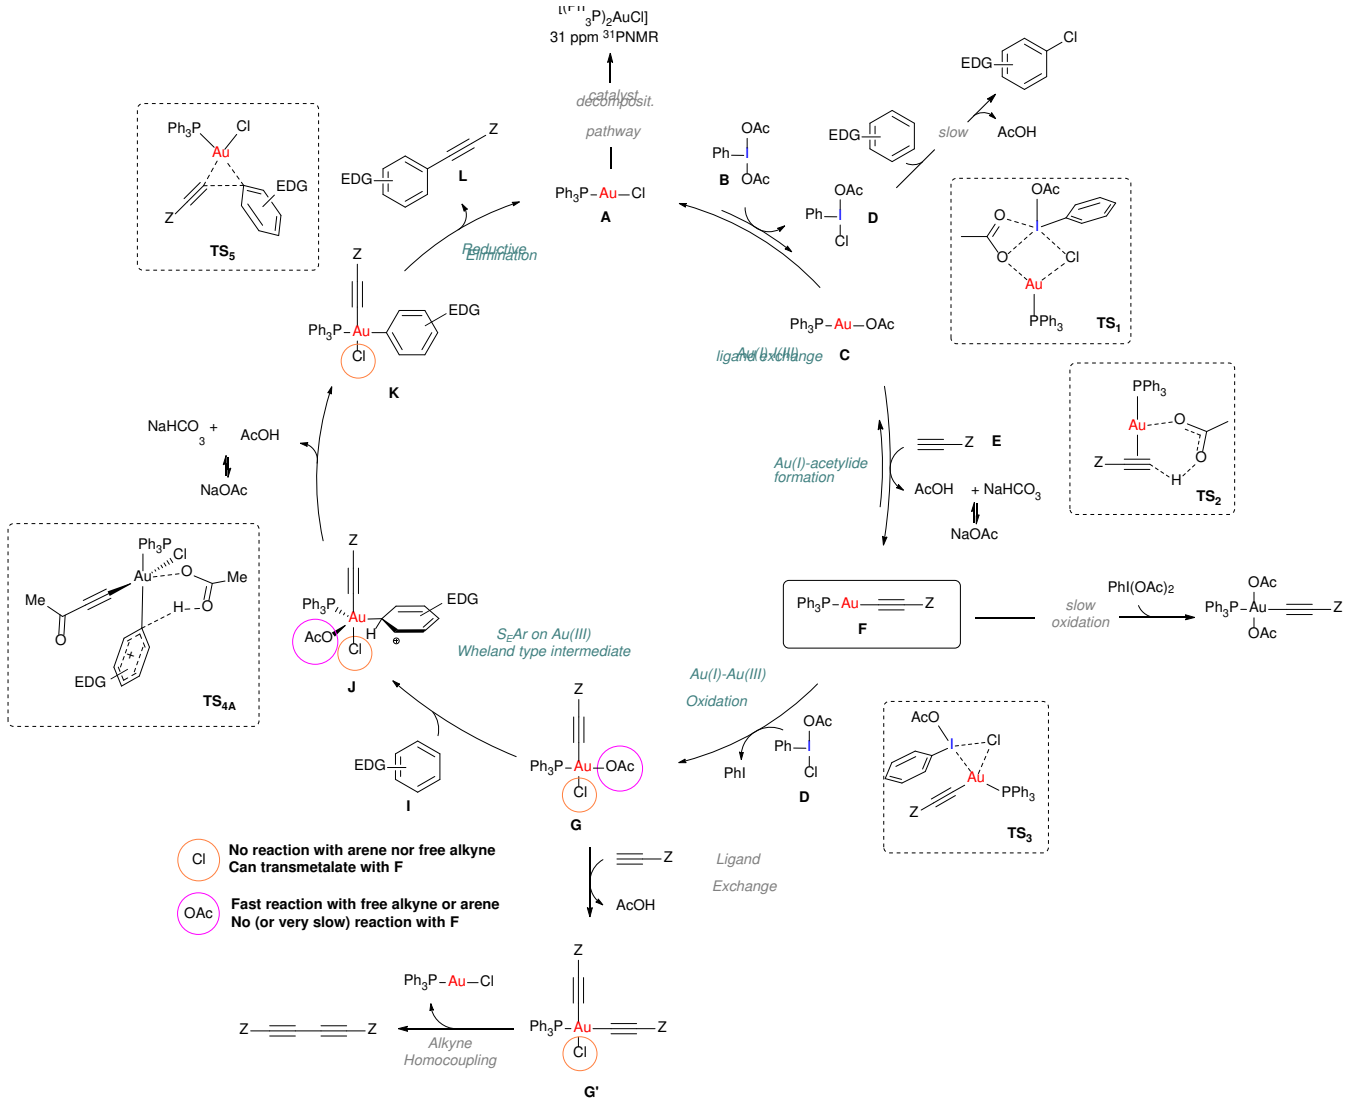
Finally, DFT calculations were carried out to map the entire energy potential surface (Figure 5). The mixture of free alkyne, $PhI(OAc)_2$ and Ph_3PAuCl was taken as the ground state of energy (G = 0 kcal/mol), mimicking the initial experimental conditions. As detailed in Figure 5, the Cl/OAc anion exchange between the gold and the iodine centers through **TS_1** (with Au-O_1 and I-Cl bond distances of 2.35 and 2.90

Å respectively) leads to a first high energy mixture, **INT_1** (+12.8 kcal/mol), which is readily transformed into **INT_2** (+6.3 kcal/mol) by deprotonation of the alkyne, alkynyl-gold complex formation and HOAc release via **TS_2** (with bond distances: Au-C_1 = 2.34 Å, Au-O_1 = 2.46 Å and C_1-H = 1.23 Å).[29] The oxidation of the alkynyl-gold complex by the active oxidant species PhI(OAc)(Cl) presents an affordable activation energy (+20.1 kcal/mol from **INT_2** to **TS_3**), involving the rupture of the I-Cl bond (I-Cl = 3.10 Å, Au-Cl = 2.67 Å, Au-I = 3.32 Å and Au-C_1 = 2.0 Å). The alternative Au(I) to Au(III) oxidation involving the I-OAc bond of PhI(OAc)(Cl) is disfavoured by more than 8 kcal/mol with respect to **TS_3** (Figure 3d). After the oxidation via **INT_3**, iodobenzene is released to form a highly stable neutral intermediate **INT_{5A}** (- 17.9 kcal/mol).

The arene reacts then with **INT_{5A}** and the acetate ligand abstracts the proton to restore the aromaticity via **TS_{4A}** in an overall highly exergonic process to give **INT_6** (-29.7 kcal/mol from **INT_3**), which is followed by a fast reductive elimination (the energy profile calculated for a dissociative interaction of the arene with **INT_3** can be found in Figure S69 in the SI).[15] Deuterium labelling experiments on



Scheme 3. Mechanistic Proposal for the Au-catalyzed Alkynylation of Arenes**.** Structures of **TS_1**, **TS_2**, **TS_3** and **TS_5** stem from DFT calculations reported in Figure 5.

the arene carried out in our seminal study[7] showed no primary KIE, in line with the present DFT results in which arene auration is not turnover limiting. Ph_3PAuCl is formed in the final stage, re-entering the cycle, which shows an overall reaction energy of -81 kcal/mol. Thus, the DFT calculations support the hypothesis of the transformation of gold(I)-chloride into gold(I)-acetate (**INT_1**), and this into Au(I)-acetylide (**INT_2**) through two up-hill equilibria. The activation energies for these processes are comparable to that of the subsequent oxidation step by the in situ generated PhI(OAc)(Cl) via transition state **TS_3** and also to that of the attack of the arene onto the alkynyl-gold(III) intermediate via **TS_{4A}**. DFT calculations also confirmed the lability of aryl-aurate intermediate (**INT_6**), which rapidly evolves via reductive elimination towards the cross-coupling product regenerating the Ph_3PAuCl catalyst.[23,30]

Proposed Catalytic Cycle

The data presented in previous sections enabled a more detailed mechanism for the Au-catalyzed alkynylation of arenes to be proposed based on a better understanding of both oxidant and catalyst speciation for a productive reaction outcome (Scheme 3).

On the outset of the reaction, the formation of a Au(I)-acetylide complex **F** takes place. However, the reaction of methyl propiolate (**E**) and Ph_3PAuCl in the presence of base to give acetylide complex **F** is not a favorable process (Figure 2b). In contrast, the same reaction in the presence of $PhI(OAc)_2$ revealed the formation of **F** after only 5 minutes (Figure 2c), in line with the spectroscopic analysis of a catalytic reaction (Figure 2a). These results led us to discard a facile equilibrium between the Au pre-catalyst and the alkyne while suggesting a new role for the oxidant in the initial steps of this transformation. Studies, including F-labeling experiments and DFT calculations support a mechanistic scenario involving multiple equilibria between alkyne, oxidant and gold. Initially, a ligand exchange between Ph_3PAuCl and $PhI(OAc)_2$ delivers $Ph_3PAuOAc$ and a nonsymmetric oxidant, PhI(OAc)(Cl). As shown in Figure 2d and Figure 3a-b, free alkyne reacts with the trace amounts of $Ph_3PAuOAc$ to give Au(I)-acetylide complex **F** and acetic acid, which is quenched in the presence of $NaHCO_3$. Experimentally, the formation of a non-symmetric hypervalent iodine *m*-F-PhI(OAc)(Cl) (**21**) could also be monitored by ^{19}F NMR (Figure 4). This new oxidant formed *in situ* present a lower activation energy towards the oxidation of **F** into Au(III)-acetylide complex **G** compared to $PhI(OAc)_2$ ($\Delta\Delta G^{\ddagger}$ ca. 9

kcal/mol, Figure 3d). Experiments summarized in equations 2, 7, 8 and 9 clearly suggest that free alkyne favors a productive reaction outcome and also that $PhI(OAc)_2$ is not an efficient oxidant for **8** nor the putative $Ph_3PAu(C{\equiv}C\text{-}CO_2Me)(OAc)_2$ (**9**) complex is a highly competent reaction intermediate. Still, alternative reaction pathways operating with $PhI(OAc)_2$ as oxidant cannot be completely ruled out (equation 9). Putative analogues of Au(III) complexes **G** (**10** and **13** in Table 1) were used as mechanistic probes in stoichiometric experiments which revealed the crucial role of anionic ligands in the reaction outcome. Thus, acetato ligands on the Au(III) center can be rapidly exchanged in the presence of arenes whereas the corresponding chlorides remain unreacted.

A competitive OAc/alkyne exchange in **G** to give **G'** can occur although in a sufficiently slower rate to enable a productive cross coupling reaction rather than the undesired homocoupling of alkyne, which is sometimes observed as minor by-product in these transformations. Although a Au(I)/Au(III) transmetalation involving the chloride ligands towards the formation of a bis-alkynyl Au(III) intermediate cannot be completely ruled out,[18,31] control experiments indicate that this process might be slow under the present reaction conditions (see Figure 4c and Figure S51-57 in the SI).

The proposed Au(Cl)-I(OAc) exchange in the first steps of the reaction produces a "non-symmetric" ArI(Cl)(OAc) oxidant responsible for reaction by-products stemming from the direct oxidation (i.e. chlorination) of the arene (< 5%) (section 4.2 in SI).[32] Finally, the mechanism for catalyst decomposition has also been studied. Slow de-coordination of Ph_3P from the neutral starting complex Ph_3PAuCl or other phosphine-Au species involved in the reaction results in the formation of trace amounts of $(Ph_3P)_2AuX$ (**7**) visible in the ^{31}P NMR of the standard catalytic reaction media (Figure 2a). Control experiments revealed that these species are catalytically inactive and do not interfere with a productive reaction outcome (see section 4.3 in the SI).[33]

Conclusions

A detailed investigation of the gold-catalyzed alkynylation of arenes including kinetic and stoichiometric experiments together with DFT calculations has provided an insightful perspective on the mechanism of this transformation. A ligand exchange involving alkyne, Au(I)-catalyst and oxidant is needed to form both, a Au(I)-acetylide complex as well as a more reactive "non-symmetric" oxidant PhI(OAc)(Cl) responsible for the crucial Au(I)/Au(III) turnover. Both processes, i.e. the formation of Au(I)-acetylide and its oxidation, are connected through an equilibrium which evolves along the reaction progress. Reaction of the electron rich arenes with the in situ generated Au(III)-alkynyl intermediate occurs to produce a short-lived aryl-alkynyl-Au(III) complex, which evolves by reductive elimination to produce the observed cross-coupling products and the Au(I) catalyst. The mechanisms of both, catalyst decomposition and competing side reactions, have also been unraveled.

Few of the lessons learned in this study may also be applicable to other gold-catalyzed oxidative cross-couplings employing I(III) oxidants. Unexpectedly, a ligand exchange between the gold(I) pre-catalyst and the initial hypervalent iodine might be key to produce the suitable gold(I)-species to enable activation of the alkyne in the first place. Furthermore, the same process provides the appropriate oxidizing species, capable to produce reactive Au(III)-intermediates. This process is influenced by both, the nature of the ancillary ligand on gold as well as by the presence of other reaction partners which can shift this up-hill equilibria. Oxidation is also an energetically demanding process which translates into a Au(III)-intermediate, whose reactivity will be fine-tuned by the nature of the anionic ligands transferred by the oxidant: while acetato ligands favor activation of the arene and are easily displaced to give the cross-coupling products, chlorides are much less reactive and thus stabilize these species favoring transmetalation processes. We believe this mechanistic study supporting Au(I)/Au(III) redox catalytic cycles provides novel insights, useful not only for the development of new gold catalyzed oxidative transformations but also for the improvement and fine tuning of already available ones.
